

Crop value

This is a measure of the success and therefore the acceptability of the yields and quality obtained. The higher the yield and/or quality the greater the acceptability.

Some things to consider:

- Opportunity costs when implementing the practice(s), for example if you take strips of land out of production to install natural habitat to support natural enemies.
- An increase in crop value due to new markets available, for example by producing pesticide-free products

Direct costs

This is a measure of the value delivered against the cost of the package.

Some things to consider:

- Does it require upfront costs that take time to see a return on investment, for example buying a mechanical weeding implement.
- Does it require time before the return on investment is realized, or is it realized immediately, for example planting of a diverse flower buffer versus re-establishing native habitat.

Environmental impact

Please consider **both** the pesticides and non-pesticide based impacts in this assessment. The environmental costs from pesticides can be calculated from the pesticide application data using the Pesticide Impact Explorer (PIE) tool: agro.au.dk/pietool

Some things to consider:

- Does the practice impact greenhouse gas emissions, for example by requiring more tractor passes
- Does the practice impact water quality, for example by reducing nitrogen applications
- Does the practice support biodiversity, for example by establishing flower strips along field borders

Human health and safety

Please consider **both** the pesticides and non-pesticide based impacts in this assessment. The human health costs from pesticides can be calculated from the pesticide application data using the Pesticide Impact Explorer (PIE) tool: agro.au.dk/pietool

Some things to consider:

- Exposure to physical risks, such as the use of ladders when implementing the practice
- Does it involve activities that must be done at night, or during the heat of the day

- You should think about health and safety issues not relating to the use of pesticides – there is an additional tool (Pesticide Impact Explorer (PIE) that allows you to enter the pesticide applications and get a numeric estimate of risk, as well as societal costs

Time and management

The impact of implementing the package on time and management considerations, outside of those captured by direct costs.

Some things to consider:

- Does the practice require certain skills or training?
- Does the practice require careful timing of application?

Third party coordination requirements

Whether implementation requires additional supply chains, infrastructure, or cooperation that may be outside of the user's direct control.

Some things to consider:

- Can a producer implement the practice(s) immediately, or do they require training to run a spot sprayer
- Can the producer implement it now, or do they need to hire a third-party to, for example, spray pesticides using a drone
- Does the practice require establishment of supply chains, for example a new biological control agent or a new crop variety
- Does the practice require coordination with neighbors, for example establishment of buffer areas
